We propose a model of a financial market with multiple assets that takes into account the impact of a large institutional investor rebalancing its positions so as to maintain a fixed allocation in each asset. We show that feedback effects can lead to significant excess realized correlation between asset returns and modify the principal component structure of the (realized) correlation matrix of returns. Our study naturally links, in a quantitative manner, the properties of the realized correlation matrix — correlation between assets, eigenvectors and eigenvalues — to the sizes and trading volumes of large institutional investors. In particular, we show that even starting with uncorrelated “fundamentals”, fund rebalancing endogenously generates a correlation matrix of returns with a first eigenvector with positive components, which can be associated to the market, as observed empirically. Finally, we show that feedback effects flatten the differences between the expected returns of assets and tend to align them with the returns of the institutional investor’s portfolio, making this benchmark fund more difficult to beat, not because of its strategy but precisely because of its size and market impact.

Keywords: Liquidity; feedback effects; institutional investors; endogenous correlations.

1. Introduction

International financial markets have become increasingly dominated by large institutional investors — mutual funds, insurance companies, pension funds — which account for a large fraction of holdings and trades in financial assets. For instance, institutional investors in the US hold $25000 billion in financial assets, which represents 17.4% of total outstanding assets. Their positions in the US equity markets amount to $12500 billion, which corresponds to holding 70% of the total equity assets in the US (Gonnard et al. 2008, Tonello & Rabimov 2010). Two major features
characterize large institutional investors over the last years. First, they build their portfolios with the use of indices and exchange-traded funds (representing a sector, a geographical zone or an asset class for instance), which have become increasingly popular in the last years, and assets traded on large national exchanges (Gastineau 2010, Fuhr 2011, Boudreaux 2012). Secondly, while such asset managers do not frequently modify their allocations, they do actively trade in the market: Carhart (2012) documents that the average turnover for US mutual funds is 75%.

Large institutional investors build and manage their portfolios comprising numerous assets taking into account the dependence structure between asset returns. In particular, the correlation between asset returns is a key ingredient for trading, portfolio optimization and risk management. It is very often considered as reflecting a structural correlation between fundamentals of asset returns and hence assumed not to vary a lot in time. Ever since Markowitz (1952), theoretical studies show that, under the assumption of a constant correlation structure between asset returns, optimal strategies are fixed-mix strategies, i.e. maintaining a fixed allocation in each asset in the portfolio. Typically, if the value of an asset increased, its weight in the portfolio increases and the investor following a fixed-mix strategy sells part of its positions in this asset, so as to come back to the target allocation for this asset. The fixed-mix strategy implies “buying low and selling high”. Numerous theoretical studies (Evstigneev & Schenk-Hoppé 2002, Dempster et al. 2003, Mulvey & Kim 2008) have shown that such strategies can enhance the long-term growth rate of portfolios.

Whereas, the price of financial assets is traditionally modeled as an exogenous stochastic process unaffected by investor strategies, the presence of institutional investors, typically following fixed-mix strategies and which have a large impact when trading, has implications for financial markets, in particular for the indices and ETFs that they trade, and hence for the components of those indices and ETFs.

Indeed, many empirical studies, such as Aitken (1998), Sias (1996), Sias & Starks (1997), detailed in Sec. 1.2, document the impact of large institutional investors. They show in particular that trading by institutional investors tends to increase the correlation between the assets that they hold and generate contagion effects to other investors with similar balance sheets. In addition, the study of empirical correlation matrices (Friedman & Weisberg 1981, Bouchaud et al. 2000) shows that the realized correlation matrix of returns displays common features across stock markets — first eigenvalue which is significantly larger than the others and associated to a “market” eigenvector, with positive weights on each component, as shown in Fig. 1 in the case of the Eurostoxx 50 — which strongly suggest the impact of institutional investors on the dependence structure of asset returns.

The main contribution of this theoretical paper is to quantify the feedback effects induced by the rebalancing of a large institutional investor on the dependence structure of asset returns (realized covariances and correlations of asset returns, eigenvalues and eigenvectors of the realized correlation/covariance matrix of returns) and their implications in terms of spillover effects and portfolio allocations for other
Institutional Investors and the Dependence Structure of Asset Returns

1.1. Summary

We propose a multi-period model of a financial market with multiple assets, in which a large institutional investor maintains a fixed allocation across assets. Simulations of this model, with realistic parameters estimated from time series of S&P500 stock returns, suggest that feedback effects from the fund’s rebalancing lead to a significant increase in realized correlation between asset returns. We exhibit conditions...
under which the discrete-time model converges to a diffusion limit. By studying the multi-dimensional diffusion limit for the price dynamics, we show that the presence of a large institutional investor maintaining a constant allocation across asset classes may result in a significant and systematic impact on expected returns and the correlation of returns. In particular, fixed-mix strategies dampen asset volatility but increase correlation across asset classes. This rebalancing effect leads to a systematic bias in the first principal component of the correlation matrix, overweighting assets with high turnover in the benchmark portfolio. In particular, in the presence of feedback effects, and even starting from uncorrelated fundamentals, trading by the large fund endogenously generates a realized correlation matrix of returns with a first eigenvector with positive components. The impact of the large institutional investor biases asset expected returns and decreases the performance of funds who overweight (respectively, underweight) assets with large (respectively, low) expected returns. These findings have consequences for risk-management and asset allocation. We show that the impact of the large institutional investor modifies the risk/return trade-off of portfolios composed from the same assets: an investor who factors these effects into his allocations can improve his risk/return trade-off.

1.2. Related literature

Various empirical studies attest to the large market share of institutional investors. Gonnard et al. (2008) study institutional investors of countries of the Organization for Economic Co-operation and Development (OECD) while Tonello & Rabimov (2010) focus on the institutional investors in the US. Such investors comprise mutual funds, insurance companies and pension funds. Their investments amounted to $40000 billion for funds in the OECD in 2005, which represents 150% of the gross domestic product of the OECD. US institutional investors account for more than half of those investments ($25000 billion) and prefer investing in equity markets (50% of their positions).

The preferences of large institutional investors are examined in numerous empirical studies. Del Guercio (1996) finds empirically that banks, contrary to mutual funds, prefer investing in prudent stocks. Gompers & Metrick (2001) use a database with seventeen years of data on large institutional investors and show that they prefer holding liquid assets, while Ferreira & Matos (2008) find that institutional investors have a strong preference for the stocks of large firms and firms with good governance. Falkenstein (2012) shows that mutual funds prefer investing in liquid stocks with low transaction costs and are averse to stocks with low idiosyncratic volatility. Lakonishok et al. (1992) study the types of strategies followed by institutional investors and whether they follow trading practices which are potentially destabilizing for asset prices. The impact of institutional investors on asset returns is widely studied in the empirical literature. Aitken (1998) shows that the growth of capital invested by mutual funds and other institutional investors in emerging markets resulted in a sharp increase of autocorrelation for the assets in those markets.
Institutional Investors and the Dependence Structure of Asset Returns

Sias & Starks (1997) also finds that the larger the institutional ownership of a stock in the NYSE, the larger its autocorrelations while Sias (1996) finds that an increase in ownership by institutional investors on a given stock results in a greater stock volatility.

Most theoretical studies model the impact of large institutional investors on a single asset’s return and volatility. Almgren & Chriss (2000), Almgren & Lorenz (2006) and Almgren (2009) model the permanent and temporary impact of a large investor liquidating a position on a single asset and derive an optimal liquidation strategy. Alfonsi et al. (2009) derive the optimal strategy to liquidate a large position on an asset by taking into account the order book of the asset. Gabaix et al. (2006) propose an equilibrium model which takes into account the supply and demand of a large institutional investor and show that their trades can lead to volatility spikes. They derive an optimal strategy for the institutional investor, in the presence of its own feedback effects. These theoretical studies explain quantitatively the facts described in the empirical literature cited previously, but mainly focus on a single asset and derive optimal strategies for institutional investors. In particular, they do not model the cross-asset impact of large institutional investors and the spillover effects that they can generate. Kyle & Xiong (2001) study a market with two risky assets and three types of traders: noise traders, convergence traders and long-term investors. They show how the strategies implemented by each type of traders can result in contagion effects and lead to endogenous correlation which can not be explained by assets fundamentals.

Our quantitative results show that, even starting from homoscedastic fundamentals, rebalancing by institutional investors naturally generates heteroscedasticity in the covariance structure of asset returns, hence giving an economic explanation for the variability of correlations and volatilities observed in financial markets and which have been modeled, in an exogenous way, by various theoretical studies (Engle 2002, Da Fonseca et al. 2008, Gouriéroux et al. 2009, Stelzer 2010, Da Fonseca et al. 2013). In addition, we find that in the presence of feedback effects from institutional investors, the realized correlation matrix of returns displays the features verified by empirical correlation matrices: the first eigenvalue is significantly higher than the other eigenvalues and is associated to an eigenvector with positive components.

While studies using random matrix theory such as Bouchaud et al. (2000) are able to explain the emergence of a dominant eigenvalue for realized correlation matrices, such studies generally lead to a first eigenvector which is invariant by rotation, and hence fail to account for the fact that the first eigenvector is a “market” eigenvector, with positive weights on each component.

1.3. Outline

This paper is organized as follows. Section 2 presents our framework for modeling the impact of trading by a large institutional investor on asset returns. Section 3 studies the dependence structure of asset returns in the presence of feedback effects.
from the large institutional investor. Finally, Sec. 4 analyzes the impact of the large institutional investor on the risk and returns of assets and for other investors in the market.

2. Asset Dynamics in the Presence of a Large Institutional Investor

2.1. Multi-period model

Asset fundamentals: Consider a discrete-time market, where trading takes place at dates $t_k = k\Delta t$ and which comprises $n$ financial assets. The value of asset $i$ at $t_k$ is $S^i_k$. Typically, one can consider that $S^i$ is the value of an index or an ETF representing a sector, asset class or geographic zone. Between $t_k$ and $t_{k+1}$, the value of each asset moves due to “fundamentals”, represented by an IID sequence $(\xi^i_{k+1}, \xi^i_{k+2}, \ldots, \xi^i_{n})_{k \geq 0}$ of centered random variables with covariance matrix $\Sigma$. In the absence of other effects, the log-return of asset $i$ between $t_k$ and $t_{k+1}$ would be

$$\Delta t \left( m^i + \frac{\Sigma^i i}{2} \right) + \sqrt{\Delta t} \xi^i_{k+1}, \quad (2.1)$$

where $m^i$ is the “fundamental” expected return of asset $i$ and $\Sigma$ is the “fundamental” covariance matrix of asset returns. $\Sigma$ reflects the fundamental structure between the $n$ assets in the market. While most practitioners consider that the covariance matrix is constant over a time horizon typically of one year, more statistically sophisticated models have been proposed for modeling heteroscedasticity and the variability of the fundamental covariance matrix (Engle 2002, Da Fonseca et al. 2008, Gouriéroux et al. 2009, Stelzer 2010, Da Fonseca et al. 2013). In this paper, for clarity purpose only, we assume that the fundamental covariance matrix $\Sigma$ is constant. Our results can be extended to the case of a stochastic fundamental covariance matrix by means of more technicalities, which do not bring more intuition to the problem raised by this paper, namely disentangling the impact of fundamentals and fund rebalancing on the dependence structure of asset returns.

The large institutional investor: Consider now a large institutional investor/fund investing in this market and following a (long) fixed-mix strategy, maintaining a fixed allocation in each asset. As discussed in Sec. 1, the fixed-mix strategy is widely used by institutional investors, in between two allocation dates, which correspond to a time frame of several months. At each date $t_k$, the fund holds a (constant, positive) proportion $x_i$ of each asset $i$ which means that the dollar amount invested by the fund in asset $i$ at this date is equal to $x_i W_k$ where $W_k$ is the fund value/wealth at $t_k$. Denoting by $\phi^i_k$ the number of units of asset $i$ held at $t_k$, the fixed-mix strategy implies that at each date:

$$\phi^i_k S^i_k = x_i W_k. \quad (2.2)$$

At each period, the asset values may change due to fundamentals and the fund rebalances its positions in order to maintain the target proportion $x_i$ in each asset $i$. 

1650010-6
Institutional Investors and the Dependence Structure of Asset Returns

If the value of an asset increased (respectively, decreased) more than the others, the fund sells (respectively, buys) units of this asset in order to maintain a fixed portion of this asset in its portfolio. The fixed-mix strategy is a typical example of a contrarian strategy, which implies “buying low and selling high”. The rebalancing by the fund, in order to maintain its target allocation, generates a net demand of \( \phi_{k+1}^i - \phi_k^i \) units of asset \( i \) between \( t_k \) and \( t_{k+1} \), in a self-financing manner:

\[
W_{k+1} = \sum_{i=1}^{n} \phi_{k+1}^i S_{k+1}^i = \sum_{i=1}^{n} \phi_k^i S_k^i + \sum_{i=1}^{n} \phi_{k+1}^i S_{k+1}^i. \tag{2.3}
\]

**Price impact:** The rebalancing of large positions by the fund — this is the case when the fund is large — impacts prices in a nonrandom manner. The impact of large orders on asset returns has been modeled in numerous manners: linear (Obizhaeva 2011, Cont et al. 2013), square root (Bence et al. 2011), or more generally concave (Almgren et al. 2005, Moro et al. 2009). We assume that the impact of this net demand by the fund on the return of each asset \( i \) is linear and is measured by the depth \( D_i \) of the market in asset \( i \): an order of \( D_i \) shares for security \( i \) moves the price of \( i \) by one percent. Note that we choose a linear price impact for clarity purpose only, as a general price impact function leads to the same continuous-time limit as a linear price impact, as shown in Cont & Wagalath (2013a).

**The discrete-time price dynamics:** The value of asset \( i \) at date \( t_{k+1} \) has to verify:

\[
S_{k+1}^i = S_k^i \exp \left( \Delta t \left( m_i - \frac{\Sigma_{i,j}}{2} \right) + \sqrt{\Delta t} \xi_k^i + 1 + \frac{\phi_{k+1}^i - \phi_k^i}{D_i} \right). \tag{2.4}
\]

The term \( \exp(\Delta t(m_i - \Sigma_{i,j}/2) + \sqrt{\Delta t} \xi_k^i) \) corresponds to fundamentals while the term \( 1 + (\phi_{k+1}^i - \phi_k^i)/D_i \) is generated endogenously by feedback from the large investor. However, as \( \phi_{k+1}^i \) depends on \( S_{k+1}^i \) given Eq. (2.2), we have to prove that, at each period, the fund can rebalance its positions in a self-financing way so as to keep its fixed allocation i.e. verify Eq. (2.4). This is done in the following proposition.

**Proposition 2.1.** There exists a unique investment strategy which enables the fund to keep a constant proportion \( x_i \) invested in each asset \( i \) at every period \( k \), in a self-financing way and \( (S, W) \) verify Eqs. (2.2)–(2.4).

The proof of this proposition is given in Appendix A.1. At each period, the return of an asset can be decomposed into a fundamental component and a systematic component which is generated endogenously by the large fund’s rebalancing. We remark that when market depths are infinite \( (D_i = \infty) \), the fund’s rebalancing does not generate any feedback on asset returns and assets move according to “fundamentals” only, which are captured by the fundamental covariance matrix \( \Sigma \) and the fundamental expected returns \( m \).
2.2. Simulation experiments

In this section, we present some results of simulation experiments which illustrate the impact of feedback effects from a large institutional investor following a fixed-mix strategy on the realized correlation between asset returns and the principal component properties of the realized correlation matrix of returns.

Choice of parameters: We simulate the multi-period model in a simple example of homogenous fundamental volatility, correlation and expected return. In order to compare our numerical results with empirical results on the S&P500 in 2006, we choose the following realistic parameters. The simulated market comprises $n = 500$ assets and trading is possible everyday ($\Delta t = 1/250$). Each asset has a fundamental expected return $m_i = 11\%$ (equal to the return of the S&P500 in 2006) and a fundamental volatility $\sqrt{\Sigma_{i,i}} = 10\%$ (equal to the realized volatility of the S&P500 in 2006). We denote by $\rho = \Sigma_{i,j}/\sqrt{\Sigma_{i,i}\Sigma_{j,j}}$ the fundamental correlation between any pair of assets.

We consider an institutional investor maintaining a constant portion $x_i = 1/n = 0.2\%$ invested in each asset $i$ and the initial position of the fund in each asset is equal to one fifth of the respective asset market depth: for all $i$, $\phi_0^i/D_i = 1/5$. This choice is legitimated by empirical studies: Tonello & Rabimov (2010) show that the size of institutional investors over the last years is approximately $25000$ billion, among which $50\%$, i.e. $12500$ billion are invested in US equity markets. As a proxy of market depth, we use, following Obizhaeva (2011),

$$D = \text{Average Daily Volume} / 0.33 \times \text{Daily Volatility}.$$  \hbox{(2.5)}

Given that in 2006 the average daily volume of the US equity market was $80$ billion and the realized volatility of the S&P500 was $10\%$, we find that the depth of the US equity markets is

$$\frac{80}{0.33 \times \frac{10\%}{\sqrt{250}}} \approx 38000\text{ billion.}$$  \hbox{(2.6)}

Assuming, for example, that $60\%$ of the institutional investors follow a fixed-mix strategy, this legitimates our choice of

$$\frac{\phi_0^i}{D_i} = 60\% \times \frac{12500}{38000} = \frac{1}{5}.$$  \hbox{(2.7)}

Note that we choose to compare our numerical results to empirical results on the S&P500 in 2006 because the recent financial turmoil started in 2007 and, since then, the US equity market was subject to major fire sales and deleveraging phenomenon, which were the main source of feedback in those markets, as analysed in Cont & Wagalath (2013a).

For each of the 10000 simulated scenarios, we compute the realized volatility of asset returns and the realized correlation between asset returns. The following figures display the distribution of those quantities, in the case of $\rho = 0$. We compare...
Institutional Investors and the Dependence Structure of Asset Returns

Fig. 2. Distribution of realized correlation between assets 1 and 2 (with $\rho = 0$) with and without feedback effects. The X-axis represents the value of the realized correlation and the Y-axis the associated probability.

those distributions to the case without feedback effects, which corresponds to the case when market depths are infinite.

Realized correlation and realized variance: Figure 2 shows that the institutional investor’s strategy increases realized correlation between asset returns. Whereas without feedback effects, the distribution of realized correlation between the two assets is centered around its fundamental value $\rho = 0$, we witness, in the presence of feedback effects, that the distribution of realized correlation is shifted towards positive values, centered around an average value of 10% and with values over 20% with significant probability. Even starting with zero fundamental correlations, feedback effects generate, on average, a realized correlation of 10% between assets. In addition, numerical experiments show that the price impact of fixed-mix strategies decreases asset volatility: starting from fundamental asset volatilities of 10% and a fundamental correlation parameter $\rho = 0$, realized volatilities of asset returns are centered around a value of 7%. This is due to the fact that the fund follows a “contrarian” strategy: it buys (respectively, sells) assets that decreased (respectively, increased) the most, hence dampening their decrease (respectively, increase) and, overall, dampening the amplitude of price moves.

Average pairwise realized correlation and highest eigenvalue of the realized correlation matrix: Table 1 displays the average for the average pairwise realized correlation over $10^4$ simulations, for different values of fundamental correlation $\rho$ and fund sizes $\phi_i/D_i$. It shows that, for each choice of parameters, due to the impact of the large investor, the average pairwise correlation is higher than its

correlation of 15%, which corresponds to a fundamental largest eigenvalue of 76, combined to feedback effects, in the case where $\phi_0^i/D_i = 1/5$.

2.3. Continuous-time limit

We now analyze the continuous-time limit of the multi-period model: the study of this limit enables to obtain analytical formulas for realized correlation between asset returns, eigenvalues and eigenvectors of the realized correlation matrix and asset expected returns, which confirm quantitatively the effects observed in the numerical experiments.

The following theorem describes the diffusion limit of the price process.

**Theorem 2.2.** Under the assumption that there exists $\eta > 0$ such that:

$$E(\|\exp(\eta \xi)\|) < \infty \quad \text{and} \quad E(\|\xi\|^{q+4}) < \infty,$$

(2.8)

the process $(S_t, W_t)_{t \geq 0}$ converges weakly to a diffusion process $(P_t, V_t)_{t \geq 0}$ as $\Delta t$ goes to 0 with:

$$dP_t^i = b_i(P_t, V_t)dt + (a(P_t, V_t)dB_t)_i, \quad 1 \leq i \leq n,$$

(2.9)

$$dV_t = b_{n+1}(P_t, V_t)dt + (a(P_t, V_t)dB_t)_{n+1},$$

(2.10)

where $B_t$ is an $n$-dimensional Brownian motion and $a$ (respectively, $b$) is a $M_{n+1 \times n}(\mathbb{R})$-valued (respectively, $\mathbb{R}^{n+1}$-valued) mapping such that

$$a_{i,j}(S, W) = \sum_{l=1}^{n} \frac{\partial \theta_i}{\partial z_l}(S, W, 0) \times \sqrt{\Sigma_{i,j}},$$

(2.11)

$$b_i(S, W) = \sum_{j=1}^{n} \frac{\partial \theta_i}{\partial z_j}(S, W, 0) \overline{\mu}_j + \frac{1}{2} \sum_{j=1}^{n} \sum_{l=1}^{n} \frac{\partial^2 \theta_i}{\partial z_j \partial z_l}(S, W, 0) \overline{\Sigma}_{j,l},$$

(2.12)

where $\theta$ is defined in Lemma A.1, $\overline{\mu}_i = m_i - \Sigma_{i,i}/2$ and $\sqrt{\Sigma}$ is a square-root of the fundamental covariance matrix.

In the continuous-time limit, at each date $t$, the fund allocates $x_i$ to asset $i$. Its holdings in asset $i$ are:

$$\phi_t^i = \frac{x_t V_t}{P_t^i}.$$  

(2.13)

The proof of this theorem is given in Appendix A.2. $a$ and $b$ can be computed explicitely from Lemma A.3 and Lemma A.4 in Appendix A.2. Theorem 2.2 enables to quantify, in a tractable manner, the impact of the large fund on asset dynamics. In the next sections, in order to characterize this impact more intuitively, we will study the impact at order one in liquidity, which enables us to decompose realized correlations, eigenvalues, eigenvectors and fund volatility into a stationary fundamental part and a liquidity-dependent and path-dependent part, generated endogenously by the large institutional investor.
In the case where market depths are infinite (for all $i$, $D_i = +\infty$), the expression for $a$ and $b$ simplifies to

$$a_{i,k}(P,V) = P^i \sqrt{\Sigma_{i,k}} \quad \text{and} \quad b_i(P,V) = P^i m_i, \quad 1 \leq i \leq n,$$

(2.14)

where $A$ is a square root of $\Sigma$ and asset prices follow a multivariate Black and Scholes dynamics with expected return $m$ and covariance matrix $\Sigma$:

$$\frac{P^i}{P_0^i} = \exp \left( \left( m_i - \frac{\Sigma_{i,i}}{2} \right) t + \sqrt{\Sigma} B_t \right) \quad \text{and} \quad \frac{V_t}{V_0} = \exp \left( \left( X_m - \frac{X \Sigma X}{2} \right) t + X A B_t \right).$$

(2.15)

When market depths are finite, feedback effects from the large fund modify this fundamental price dynamics, as described in the next sections.

### 3. Dependence Structure of Asset Returns

In this section, we study the impact of the large fund’s rebalancing on the dependence structure of asset returns and we show that this structure may depend more on the type and market cap of the various strategies used by large market players than on fundamentals. The fund’s impact can be quantified by studying the realized covariance/correlation matrix of asset returns (Andersen et al. 2003, Barndorff-Nielsen & Shephard 2004).

#### 3.1. Realized covariance and correlation between asset returns

Proposition 3.1 shows that realized covariances and correlations can be decomposed into a fundamental component and an endogenous component generated by the fund’s rebalancing strategy. When the rebalancing volumes are large compared to the depth of assets, this endogenous component is exacerbated and can become significant compared to the fundamental component.

The realized covariance matrix of asset returns between $t_1$ and $t_2$, denoted $C_{[t_1,t_2]}$, is defined by

$$C_{[t_1,t_2]}^{i,j} = \frac{1}{t_2 - t_1} ([\ln P^i, \ln P^j]_{t_2} - [\ln P^i, \ln P^j]_{t_1}),$$

(3.1)

where $[\ln P^i, \ln P^j]_t$ is the quadratic covariation between $\ln P^i$ and $\ln P^j$ on $[0,t]$ and the realized correlation between $t_1$ and $t_2$ is defined by

$$R_{[t_1,t_2]}^{i,j} = \frac{C_{[t_1,t_2]}^{i,j}}{(C_{[t_1,t_2]}^{i,i} C_{[t_1,t_2]}^{j,j})^{1/2}},$$

(3.2)
Proposition 3.1. The realized covariance and realized correlation between assets $i$ and $j$ returns can be respectively decomposed as follows:

$$
C_{i,j}^{[0,T]} = \sum_{l=1}^{n} x_l (\Sigma_{j,l} - \Sigma_{i,j}) + \Lambda_i \Delta T \sum_{l=1}^{n} x_l (\Sigma_{i,l} - \Sigma_{i,j}) + O(||\Lambda||^2),
$$

(3.3)

$$
R_{i,j}^{[0,T]} = \frac{\Sigma_{i,j}}{\Sigma_{i,i} \Sigma_{j,j}} + \frac{\Lambda_i \Delta T}{\sqrt{\Sigma_{i,i} \Sigma_{j,j}}} \sum_{l=1}^{n} x_l \left(\frac{\Sigma_{j,l}}{\Sigma_{j,j}} - \frac{\Sigma_{i,j}}{\Sigma_{i,i}}\right) + O(||\Lambda||^2),
$$

(3.4)

where $\Lambda$ is an $n$-dimensional vector representing the initial holdings of the fund in asset $i$ as a fraction of market depth:

$$
\Lambda_i = \frac{\phi_i^0}{D_i},
$$

(3.5)

and $\Delta T$ is a measure of the volume traded on asset $i$ by the large fund:

$$
\Delta T = 1 + \int_0^T \left(1 - \frac{s}{T}\right) \frac{d\phi_i^0}{\phi_i^0} = \frac{1}{T} \int_0^T \phi_i^0 ds > 0
$$

(3.6)

and $\mathbb{E}(O(||\Lambda||^2)/||\Lambda||^2)$ is bounded when $\Lambda$ goes to zero.

The proof of this corollary is given in Appendix A.3. In the presence of feedback effects, the realized covariance/correlation matrix is the sum of the fundamental covariance/correlation matrix and an excess realized covariance/correlation matrix generated by the impact of the fund’s rebalancing strategy.

The magnitude of the institutional investor’s impact on asset returns is naturally measured by the quantities

$$
\Lambda_i = \frac{\phi_i^0}{D_i},
$$

(3.7)

which represent the size of the institutional investor’s positions in each asset, as a fraction of asset market depth and Proposition 3.1 gives the expansion at order one in $||\Lambda||$ of the realized covariances and correlations.

Equation (3.4) shows that realized correlations between asset returns are impacted by the strategy followed by the institutional investor, namely its size in each asset as a fraction of market depth ($\Lambda_1, \ldots, \Lambda_n$), its allocations ($x_1, \ldots, x_n$) and its rebalancing strategy ($\Delta T^1, \ldots, \Delta T^n$).

They can deviate significantly from fundamentals when the size of the fund’s positions and trading volumes are large compared to asset market depths. As the size of institutional investors and their market shares has become very large over the last years, as discussed in Sec. 1, Proposition 3.1 shows that the dependence structure of asset returns may depend more on the type and market cap of the various strategies used by large market players than on fundamentals.
We remark that when the fund invests significantly in one asset $i_0$, such that $\Lambda_{i_0} > 0$, and even if its positions on the other assets are negligible ($\Lambda_i = 0$ for $i \neq i_0$), the realized covariance between those assets and $i_0$ is modified and different from the fundamental covariance, generating a contagion effect from this asset to all other assets held by the fund.

### 3.2. Case of zero fundamental correlations

In this section, we examine the case when the fund invests in assets with zero fundamental correlations: the fundamental covariance matrix $\Sigma$ is diagonal and we write:

$$\Sigma_{i,i} = \sigma_i^2 \quad \text{and} \quad \Sigma_{i,j} = 0, \ i \neq j. \quad (3.8)$$

We show that rebalancing by the large fund endogenously generates positive realized correlation between assets with zero fundamental correlation, reducing the benefits of diversification for the fund. The presence of the fund induces a minimum structural realized correlation between asset returns, which depends on liquidity and rebalancing flows. Even starting from a fundamental correlation matrix which is the identity, feedback effects from the large fund naturally lead to the empirically observed structure for realized correlation matrices: a dominant eigenvalue, which is of the order of the number of assets in the market $n$, and associated to an eigenvector with strictly positive components, corresponding to the market.

Using Eq. (3.4), we can compute the realized correlation between assets $i$ and $j$ returns in the case of zero fundamental correlations:

$$R_{i,j}^{[0,T]} = \Lambda_i \frac{\sigma_j x_j}{\sigma_i} \Delta \Phi_T^i + \Lambda_j \frac{\sigma_i x_i}{\sigma_j} \Delta \Phi_T^j + O(\|\Lambda\|^2) > 0. \quad (3.9)$$

Equation (3.6) implies that $\Delta \Phi_T^i > 0$ and we deduce that feedback effects from the fund’s rebalancing generate positive realized correlation between assets with zero fundamental correlations. Intuitively, this stems from the fact that the systematic strategy used by the fund creates a similar pattern of behavior for all assets and shows that diversification effects are reduced by the fund’s own impact. This analytical result confirms quantitatively the numerical results of Fig. 2. Excess correlation is exacerbated by the size of the fund relative to market depth ($\|\Lambda\|$) and the volumes of rebalancing ($\Delta \Phi$), which are endogenously determined by the fund’s strategy $(x_1, \ldots, x_n)$. Our results show that when liquidity effects are accounted for, observed levels of realized correlation across assets are compatible with the null hypothesis of absence of correlation in fundamentals.

Equation (3.9) enables to derive a structural minimum for the realized correlation between a given pair of assets $i$ and $j$:

$$R_{i,j}^{[0,T]} \geq 2 \sqrt{\Lambda_i \Lambda_j (\Delta \Phi_T^i \Delta \Phi_T^j)^2} + O(\|\Lambda\|^2). \quad (3.10)$$

This lower bound for realized correlation is triggered by the mere presence of the institutional investor following a fixed-mix strategy. In particular, the more the fund
Institutional Investors and the Dependence Structure of Asset Returns

invests in two assets, the greater the correlation it generates endogenously between the two assets.

As the realized correlation matrix \( R_{[0,T]} \) has strictly positive terms, the Perron Frobenius theorem states that it has an eigenvalue which is strictly higher than its other eigenvalues and which is associated to an eigenvector with strictly positive coordinates. Furthermore, this eigenvalue belongs to the interval:

\[
1 + \left( \frac{1}{n(n-1)} \sum_{i \neq j} R_{i,j}^{[0,T]} \right) \left[ 1 + \max_i \sum_{j \neq i} R_{i,j}^{[0,T]} \right].
\]  

(3.11)

The term:

\[
\frac{1}{n(n-1)} \sum_{i \neq j} R_{i,j}^{[0,T]}
\]  

(3.12)

represents the average pairwise correlation. What is remarkable is that, even starting with a fundamental correlation matrix which is equal to the identity, and hence has all eigenvalues equal to 1 and no particular structure for eigenvectors, the impact of the fund naturally generates a correlation matrix with a dominant eigenvalue, of the order of \( n \) and associated to a “market” eigenvector. Our results enable to explain quantitatively the existence of such a market vector associated to the largest eigenvalue of the correlation matrix, as illustrated in Fig. 1.

Finally, using Proposition 3.1, we find that the realized variance of asset \( i \) returns is given by

\[
C_{i,i}^{[0,T]} = \sigma_i^2 (1 - 2(1 - x_i) \Lambda_i \Delta \Phi_i^T) + O(\| \Lambda \|^2) < \sigma_i^2,
\]  

(3.13)

which implies that feedback effects decrease the realized variance of asset returns. This is consistent with the fact that the fund buys (respectively, sells) assets which decreased (respectively, increased) the most, dampening the amplitude of asset movements.

3.3. Eigenvalues and eigenvectors of the realized correlation matrix

We now analyze the principal component properties of the realized correlation matrix of returns, in the case of a general fundamental correlation matrix. Our study enables to establish a quantitative link between the eigenvalues and eigenvectors of the correlation matrix and the strategy implemented by the fund.

As the realized correlation matrix in the presence of feedback effects can be considered as a perturbation of the fundamental correlation matrix, one can expect that its eigenvalues and eigenvectors are also perturbations of the corresponding eigenvalues and eigenvectors of the fundamental correlation matrix. Recall that the realized correlation matrix \( R_{[0,T]} \) and the fundamental correlation matrix \( \tilde{R} \) are
real-valued matrices defined respectively by:

\[ R^{i,j}_{[0,T]} = \frac{C^{i,j}_{[0,T]}}{(C^{i,i}_{[0,T]}C^{i,j}_{[0,T]})^{1/2}} \quad \text{and} \quad \overline{R}^{i,j} = \frac{\Sigma^{i,j}}{(\Sigma^{i,i}\Sigma^{j,j})^{1/2}}. \]  

(3.14)

As they are both symmetric and nonnegative, we know that there exist eigenvalues \( v_1 \geq \cdots \geq v_n \geq 0 \), \( \psi_1 \geq \cdots \geq \psi_n \geq 0 \) and two orthonormal bases \((\psi_1, \ldots, \psi_n)\), \((\overline{\psi}_1, \ldots, \overline{\psi}_n)\) such that for all \( 1 \leq j \leq n \):

\[ R^{[0,T]}\psi_j = v_j \psi_j \quad \text{and} \quad \overline{R}\overline{\psi}_j = \overline{\psi}_j \psi_j. \]

(3.15)

The following proposition gives analytical formulas which quantify the impact of the large institutional investor on the principal component properties of the realized correlation matrix \( R^{[0,T]} \).

**Assumption 3.2.** \( \psi_j \) defined in Eq. (3.15) is a simple eigenvalue for the fundamental correlation matrix \( \overline{R} \).

**Proposition 3.3.** Under Assumption 3.2, there exists \( \gamma > 0 \) such that if \( ||\Lambda|| < \gamma \), then \( v_j \) is a simple eigenvalue for the realized correlation matrix \( R^{[0,T]} \) and:

\[ v_j = \overline{\psi}_j + \frac{\nabla R}{\psi_j} \overline{\psi}_j + o(||\Lambda||) \]

(3.16)

and \( v_j \) is associated to the unit eigenvector \( \psi_j \), which is collinear to:

\[ \overline{\psi}_j + \sum_{k \neq j} \overline{\psi}_k \frac{\nabla R}{\psi_j - \psi_k} \psi_k + o(||\Lambda||), \]

(3.17)

where \( v_j, \overline{\psi}_j, \psi_j, \overline{\psi}_j \) are defined in Eq. (3.15), \( \nabla R \) is a symmetric matrix defined by \( [\nabla R]_{i,i} = 0 \) and for \( i \neq j \):

\[ [\nabla R]_{k,j} = \frac{\Lambda_j \Delta \Phi_j}{\sqrt{\Sigma_{i,j}^{i,i} \Sigma_{j,j}^{j,j}}} \sum_{l=1}^{n} x_l \left( \Sigma_{i,l}^{i,i} - \frac{\Sigma_{i,j}^{i,j} \Sigma_{j,l}^{j,j}}{\Sigma_{i,i}^{i,i} \Sigma_{j,j}^{j,j}} \right) + \frac{\Lambda_j \Delta \Phi_j}{\sqrt{\Sigma_{i,j}^{i,i} \Sigma_{j,j}^{j,j}}} \sum_{l=1}^{n} x_l \left( \Sigma_{i,l}^{i,i} - \frac{\Sigma_{i,j}^{i,j} \Sigma_{j,l}^{j,j}}{\Sigma_{j,j}^{j,j}} \right) \]

(3.18)

and \( o(||\Lambda||)/||\Lambda|| \) converges almost surely to zero when \( \Lambda \) goes to zero.

Proposition 3.3 is a well-known result of perturbation theory for eigenvalues and eigenvectors of symmetric matrices, analogous to the result of (Allez & Bouchaud 2012, Eq. (2.2)). It gives a tractable formula for the eigenvalues and eigenvectors of the realized correlation matrix in the presence of feedback effects from the investor following the fixed-mix strategy \((x_1, \ldots, x_n)\). Due to such feedback effects, the eigenvalues and eigenvectors of the realized correlation matrix depend on the sizes and allocations of institutional investors.

This impact naturally modifies the profile of risk in the market for all investors, and for the large institutional investor itself. Assume for example that the institutional investor, in order to reduce its volatility, has chosen a strategy \((x_1, \ldots, x_n)\)
Institutional Investors and the Dependence Structure of Asset Returns

so as to stay orthogonal to $\overrightarrow{\psi}_1$, the first eigenvector of the fundamental correlation matrix, associated to the largest eigenvalue and hence the largest regime of volatility. As a consequence, $(x_1, \ldots, x_n)$ is chosen in the subspace generated by $\overrightarrow{\psi}_2, \ldots, \overrightarrow{\psi}_n$. However, the impact of the fund’s rebalancing generates a change in the first eigenvalue, equal to:

$$\sum_{k=2}^{n} \frac{\nabla R \overrightarrow{\psi}_1 \cdot \overrightarrow{\psi}_k}{\overrightarrow{\psi}_1 \cdot \overrightarrow{\psi}_k},$$

(3.19)

whose direction is precisely in the subspace generated by $\overrightarrow{\psi}_2, \ldots, \overrightarrow{\psi}_n$, containing the vector of allocations $(x_1, \ldots, x_n)$, hence generating larger-than-expected realized volatility.

Example and numerical tests: In this paragraph, we illustrate how feedback effects impact the principal component properties of the realized correlation matrix of returns in a simple example where all parameters are homogenous: asset fundamental volatilities are equal to $\sigma$, fundamental correlation between any pair of assets is $\rho$, the large institutional investor’s allocation in each asset $i$ is $x_i = 1/n$ and the size of its position in each asset as a fraction of market depth is $\Lambda_i = \overline{\Lambda}$.

Corollary 3.4. Under the assumption of homogenous fundamental asset volatilities $\sigma$, correlations $\rho$, allocations $x_i = 1/n$ and ratios holdings to market depths $\Lambda_i = \overline{\Lambda}$, the largest eigenvalue of the realized correlation matrix of returns is equal to:

$$v_1 = 1 + (n - 1)\rho + 2\Lambda(1 - \rho) \left( \rho + \frac{1 - 2\rho}{n} - \frac{1 - \rho}{n^2} \right) \sum_{j=1}^{n} \Delta \Phi_j + o(\Lambda)$$

(3.20)

and is associated to the first eigenvector $\overrightarrow{\psi}_1$ which is proportional to:

$$\alpha_n(\Lambda) \begin{pmatrix} 1 \\ \vdots \\ 1 \end{pmatrix} + \beta_n(\Lambda) \begin{pmatrix} \Delta \Phi_1 \\ \vdots \\ \Delta \Phi_n \end{pmatrix} + o(\Lambda),$$

(3.21)

where

$$\alpha_n(\Lambda) = 1 + \overline{\Lambda}(1 - \rho) \left(-\rho + \frac{3\rho - 1}{n} + \frac{2(1 - \rho)}{n^2} \right) \sum_{j=1}^{n} \Delta \Phi_j,$$

(3.22)

$$\beta_n(\Lambda) = (n - 2)\overline{\Lambda}(1 - \rho) \left( \rho + \frac{1 - \rho}{n} \right).$$

(3.23)

Equation (3.20) shows that feedback effects increase the value of the largest eigenvalue of the realized correlation matrix. We simulated $10^4$ price trajectories of our model and, for each trajectory, we calculated numerically the largest eigenvalue.
of the realized correlation matrix and computed the theoretical largest eigenvalue given by Eq. \(3.20\). Table 3 shows that the average error made by using the theoretical formula of Eq. \(3.20\) to estimate the largest eigenvalue of the realized correlation matrix is 10\%, which is significantly lower than when using the fundamental largest eigenvalue (error of 60\%, using fundamental largest eigenvalue, which is equal to \(1 + \frac{n - 1}{\rho}\)).

Equation (3.21) gives the structure of the first eigenvector which is associated to the largest volatility mode in the market i.e. largest eigenvalue of the realized correlation matrix. Interestingly, we notice that, whereas in the absence of feedback effects and using the parameters of Corollary 3.4, the first eigenvector should be proportional to the market vector \(\mathbf{1}'(1, \ldots, 1)\), due to the impact of the fund’s rebalancing trades and in the case of a well-diversified fund \((n \text{ large})\), the first eigenvector is also driven by the vector \(\mathbf{\Delta \Phi}'(\mathbf{\Delta \Phi}_1, \ldots, \mathbf{\Delta \Phi}_n)\) which represents the (time-weighted) rebalancing volumes by the large institutional investor. In scenarios where the fund trades significantly more in one asset than in others, feedback effects generate a larger weight for this asset in the first eigenvalue of the correlation matrix.

4. Asset Returns and Fund Performance

In this section, we study the impact of the fund’s rebalancing strategy on asset and fund expected returns. Recall that, in the absence of feedback effects from the fund, the benchmark return for asset \(i\) is \(m_i\) and hence the benchmark return for the institutional investor is:

\[
\text{benchmark return for the institutional investor: } \sum_{i=1}^{n} x_i m_i. \quad (4.1)
\]

4.1. Asset expected returns

Following the same method as in Corollary 3.1, we can prove the following proposition which gives the expansion at order one in \(||\Lambda||\) of the expected return of each asset.

**Proposition 4.1.** The (instantaneous) expected return of asset \(i\) at date \(t\) in the presence of feedback effects from the institutional investor investor is:

\[
\frac{b_i(P_t, V_t)}{P_t} = m_i + \frac{\phi_i^1}{\phi_0^1} \Lambda_i \left( \sum_{l=1}^{n} x_l (m_l - m_i) \right) + O(||\Lambda||^2), \quad (4.2)
\]

where \(b_i, \Lambda\) and \(\phi_i^1\) are defined respectively in Theorem 2.2, Eq. \(3.5\) and Eq. \(2.13\).
$m_i$ is the benchmark return for asset $i$. Trading by the institutional investor generates a systematic nonfundamental component in the expected return of each asset. The nature of the fund’s impact on the expected return of asset $i$ depends on the difference between the benchmark expected return for asset $i$, $m_i$, and the benchmark expected return for the fund, given in Eq. (4.1). When $m_i$ is larger than the fund’s benchmark return, Eq. (4.2) shows that the instantaneous return for asset $i$ is lower than $m_i$ and trading by the large institutional investor decreases (respectively, increases) the expected return of assets whose benchmark expected returns are larger (respectively, lower) than the benchmark return of the fund. The fund’s rebalancing strategy endogenously dampens the difference between expected returns of assets with large fundamental expected returns (compared to the benchmark) and those with low fundamental expected returns.

Proposition 4.1 enables us to compute the expected return for the large institutional investor and for other (small) investors.

**Corollary 4.2.** At date $t$, the (instantaneous) expected return for the large institutional investor and for a (small) investor holding a portion $y_{it}$ of each asset $i$ are given respectively by

$$
\sum_{i=1}^{n} x_i m_i + \sum_{i=1}^{n} x_i A_i \phi_i \left( \sum_{i=1}^{n} x_i m_i - m_i \right) + O(\|\Lambda\|^2), \quad (4.3)
$$

$$
\sum_{i=1}^{n} y_{it} m_i + \sum_{i=1}^{n} y_{it} A_i \phi_i \left( \sum_{i=1}^{n} x_i m_i - m_i \right) + O(\|\Lambda\|^2). \quad (4.4)
$$

The expected return for the large institutional investor is lower (respectively, higher) than its benchmark return given in Eq. (4.1) if it overweighs (respectively, underweighs) assets with large fundamental expected returns. When the fund overweighs assets with large expected returns, it will generate, due to its own market impact, lower-than-expected returns.

The expected return for a small fund with positions $y_t$ is lower than the small fund’s fundamental return, which is given by:

**benchmark return for the small fund:** $\sum_{i=1}^{n} y_{t} m_i$ \quad (4.5)

when it overweighs assets with large fundamental expected returns (i.e. when $y_{t}$ is large for assets $i$ such that $m_i$ is larger than the benchmark return of the institutional investor given in Eq. (4.1)). Whereas large institutional investors are considered as benchmarks by other investors, we show that, precisely due to the large market impact of such large institutional investors, other investors who try to beat the large fund by overweighing (respectively, underweighing) assets with expected returns larger (respectively, lower) than the large fund’s benchmark will experience lower-than-expected returns. Intuitively, this is a natural consequence of Proposition 4.1 which showed that, due to feedback effects, asset returns tended to align
with the large fund’s benchmark return, hence generating lower-than-expected performance for assets with large drifts.

4.2. Optimal strategy and efficient frontier in a simple example

The following example shows how supposedly optimal strategies become sub-optimal due to the presence of large investors. When the size of the fund is significant, all investors (including the large fund itself) have to take into account the impact of the large fund when choosing their allocations.

We consider the case of a market with \( n = 2 \) assets with zero fundamental correlation and identical fundamental volatility. We write:

\[
\Sigma = \begin{pmatrix} \sigma^2 & 0 \\ 0 & \sigma^2 \end{pmatrix} \quad \text{and} \quad m = \begin{pmatrix} m_1 \\ m_2 \end{pmatrix}
\] (4.6)

and we assume, for example, that \( m_1 > m_2 \). The large institutional investor starts investing in this market and keeps a constant proportion of each asset in its portfolio, equal to 50% for each asset:

\[
X = \begin{pmatrix} 50\% \\ 50\% \end{pmatrix}.
\] (4.7)

Consider now a small fund investing in those two assets and choosing, at date \( t \), an allocation \( y_1^t \) in asset 1 and \( y_2^t = 1 - y_1^t \) of asset 2 by maximizing a mean-variance criteria. The small fund needs to estimate expected returns, variances and covariances and then calculates its allocation in each asset by solving a mean-variance criteria:

\[
y_1^t = \text{arg max} \{ U_t(y); y \in \mathbb{R} \},
\] (4.8)

where

\[
U_t(y) = y\mathbb{E}((\text{return}_1)_t) + (1 - y)\mathbb{E}((\text{return}_2)_t) - \gamma(y^2\mathbb{E}((\text{variance}_1)_t)
+ (1 - y)^2\mathbb{E}((\text{variance}_2)_t) + 2y(1 - y)\mathbb{E}((\text{covariance}_{1,2})_t).)
\] (4.9)

where \( \gamma \) is a parameter of risk aversion for the small fund.

In the presence of feedback effects from the rebalancing by the large institutional investor, using Proposition 3.1 and Proposition 4.1, we find that:

\[
U_0(y) = ym_1 + (1 - y)m_2 - \gamma \sigma^2(y^2 + (1 - y)^2) + \left( \frac{yA_1 - (1 - y)A_2}{2}m_2 - m_1 \right)
+ \gamma \sigma^2 \left( y^2A_1 + (1 - y)^2A_2 - y(1 - y)(A_1 + A_2) \right) + O(\|\lambda\|^2).
\] (4.10)

Thanks to Eq. (4.10), the following proposition follows immediately. Note that we choose to focus on date 0 for clarity purpose only.
Proposition 4.3. At date 0, the optimal allocation in asset 1, associated to the mean-variance criteria in Eq. (4.8), is given by:

\[ y_0^1 = \frac{1}{2} + \frac{m_1 - m_2}{4\gamma\sigma^2} + (\Lambda_1 + \Lambda_2)\frac{m_1 - m_2}{8\gamma\sigma^2} + \frac{\Lambda_1 - \Lambda_2}{4} + O(||\Lambda||^2). \] (4.11)

The quantity \(1/2 + (m_1 - m_2)/(4\gamma\sigma^2)\) is the optimal allocation in asset 1 in the absence of feedback effects. When there are no feedback effects, the mean variance criteria gives an optimal proportion in each asset which is constant and hence implies that the small fund’s strategy will be a fixed-mix strategy. We see that the larger the difference between the fundamental expected return of asset 1 and 2, the greater the allocation in asset 1 (recall that \(m_1 > m_2\)). When risk aversion goes to infinity \((\gamma \to \infty)\), the optimal allocations do not depend on the asset fundamental expected returns.

In the presence of feedback effects, the strategy \(1/2 + (m_1 - m_2)/(4\gamma\sigma^2)\) is no longer optimal. The presence of large institutional investors generates a nonoptimality for strategies which are optimal in the absence of feedback effects. If the small fund does not take into account the market impact of the large fund, it will choose the benchmark optimal strategy \(1/2 + (m_1 - m_2)/(4\gamma\sigma^2)\) which is not optimal. On the contrary, if the small fund estimates the fundamentals of the market (from price series when the large investor was not trading in the market) and knows the strategy of the large institutional investor (which is realistic, for example, for large mutual funds whose strategies have to be disclosed), the small fund will be able to follow the strategy \(y_t^1\) which is optimal for the mean-variance criteria in Eq. (4.8). Figure 3 shows that the efficient frontier is modified in the presence of feedback effects. We see that taking feedback effects into account enables the small investor to diminish the volatility of its portfolio for a given return. This stems from the fact that fixed-mix rebalancing induces a decrease of realized asset volatilities, as shown in Sec. 3.2, which can be used by an investor following the optimal strategy \(y_t^1\) to build a less volatile portfolio. Trading and risk-management decisions by investors need to take into account the allocations and sizes of large benchmark portfolios built by institutional investors.

In this example, feedback effects from the large fund decrease the expected return of asset 1 and increase that of asset 2. By direct computation of Eq. (4.2), we find that the instantaneous drift for asset 1 is equal to \(m_1 + \Lambda_1(m_2 - m_1)/2\) (\(< m_1\)) and that of asset 2 is equal to \(m_2 + \Lambda_2(m_1 - m_2)/2\) (\(> m_2\)). Note that those results are valid in the limit \(||\Lambda|| \to 0\), and hence asset 1 still exhibits larger expected returns than asset 2. However, the difference of expected returns between the two assets is dampened due to feedback effects, as discussed in the previous section. One could then wonder why, in Proposition 4.3, putting aside the case when \(\Lambda_2\) is significantly larger than \(\Lambda_1\), the optimal strategy in the presence of feedback effects gives a higher weight to asset 1 than without feedback effects \((y_0^1 > 1/2 + (m_1 - m_2)/(4\gamma\sigma^2))\). This is due to the fact that feedback effects also decrease the volatility of each asset.
(respectively, asset 2) at date 0 is given by $\sigma^2(1 - \Lambda_1)$ (respectively, $\sigma^2(1 - \Lambda_2)$) and hence the instantaneous Sharpe ratio of asset 1 (respectively, asset 2) is given by $m_1/\sigma \times (1 + (\Lambda_1 m_1)/(2m_2))$ (respectively, $m_2/\sigma \times (1 + (\Lambda_2 m_2)/(2m_1))$). As a consequence, we notice that feedback effects increase the Sharpe ratio of asset 1, which still has a higher expected return than asset 2: this explains the fact that the optimal strategy overweighs asset 1. However, when $\Lambda_2$ is significantly higher than $\Lambda_1$, the gain in Sharpe ratio for asset 2 is much larger than for asset 1 and hence the optimal strategy will overweigh asset 2, as stated in Proposition 4.3.

### 4.3. Trade-off between diversification and impact

The rebalancing impact described in the previous sections limits the benefits of investing in the fixed-mix strategy. Typically, large institutional investors prefer investing a significant portion of their wealth in such strategies, in order to enhance their returns, and keep a minimum portion in cash or money-market securities. We show that, whereas it is indeed favorable for the fund to diversify by investing a portion of its wealth in a fixed-mix strategy, there exists a critical size for such an investment above which the impact of rebalancing generates losses for the fund.

Consider that the fund holds a quantity $C$ of cash and it can invest a portion $\alpha \in [0, 1]$ in the fixed-mix strategy and a portion $1 - \alpha$ at the risk free rate $r$ (typically through T-Bills). Given Corollary 4.2, the expected return for the fund at date 0 is hence equal to:

$$(1 - \alpha)r + \alpha \left( \sum_{i=1}^{n} x_i m_i + \sum_{i=1}^{n} x_i \Lambda_i \left( \sum_{l=1}^{n} x_l m_l - m_i \right) \right).$$

Typically, in order to generate a large return, the fund chooses a vector of allocations $(x_1, \ldots, x_n)$ for the fixed-mix strategy which overweighs assets with large expected
returns and hence:
\[ \sum_{i=1}^{n} x_i \Lambda_i \left( \sum_{i=1}^{n} x_i m_i - m_i \right) < 0. \] (4.13)

In addition, as the fund invests a portion \( \alpha \) of its cash \( C \) in the fixed-mix strategy, we have \( \Lambda_i = \alpha C x_i / (P_0^i D_i) \). As a consequence, the expected return for the fund can be written as
\[ \alpha^2 \left( \sum_{i=1}^{n} x_i \frac{C x_i}{P_0^i D_i} \left( \sum_{i=1}^{n} x_i m_i - m_i \right) \right) + \alpha \left( \sum_{i=1}^{n} x_i m_i - r \right) + r. \] (4.14)

Note that:
\[ \sum_{i=1}^{n} x_i \frac{C x_i}{P_0^i D_i} \left( \sum_{i=1}^{n} x_i m_i - m_i \right) < 0 \] (4.15)

while
\[ \sum_{i=1}^{n} x_i m_i - r > 0. \] (4.16)

Equation (4.14) shows that the fund’s expected return is not increasing in \( \alpha \). There exists:
\[ \alpha^* = \frac{\sum_{i=1}^{n} x_i m_i - r}{2 \sum_{i=1}^{n} x_i C / P_0^i D_i (m_i - \sum_{i=1}^{n} x_i m_i)} \] (4.17)
such that the return is increasing on \([0, \alpha^*]\) and decreasing on \([\alpha^*, 1]\): when the fund starts investing in the fixed-mix strategy, such investment actually increases its expected return. The more the fund invests in the fixed-mix strategy, as long as the portion allocated is lower than \( \alpha^* \), the larger the expected return for the fund. When the fund invests more than a portion \( \alpha^* \) of its wealth in the fixed-mix strategy, its own rebalancing impact actually lowers its expected return and, the more it overweighs the fixed-mix strategy (above this weight of \( \alpha^* \)), the lower the expected return for the fund.

The critical size for the investment in the fixed-mix strategy is equal to
\[ \alpha^* C = \frac{\sum_{i=1}^{n} x_i m_i - r}{2 \sum_{i=1}^{n} x_i^2 / P_0^i D_i (m_i - \sum_{i=1}^{n} x_i m_i)}. \] (4.18)

When the fund invests more than \( \alpha^* C \) in the fixed-mix strategy, its performance will be diminished systematically by its own market impact.

**Appendix A**

We denote
\[ M_k = \begin{pmatrix} S_k \\ W_k \end{pmatrix} \in (\mathbb{R}_+^n)^{n+1} \] (A.1)

1650010-23
and

\[ Z_{k+1} = \Delta t \left( m_1 - \frac{\Sigma_{i=1}^n}{2} \right) + \sqrt{\Delta \epsilon_k} \eta_{k+1}. \]  

(A.2)

As the large fund has long positions, we know that \( x_i \geq 0 \) for all \( 1 \leq i \leq n \). In addition, we have:

\[ \sum_{i=1}^n x_i = 1. \]  

(A.3)

### A.1 Proof of Proposition 2.1

Let us show the following lemma which will imply Proposition 2.1.

**Lemma A.1.** There exists \( \theta : ([R_+^*]^{n+1} \times R^n) \to ([R_+^*]^{n+1} \times R^n) \) such that for every compact set \( K \subseteq ([R_+^*]^{n+1} \times R^n) \), there exists \( \epsilon_K > 0 \) such that \( \theta \) is \( C^\infty \) on \( K \times B(0, \epsilon_K) \) and such that for all periods \( k \geq 0 \):

\[
\left( \begin{array}{c}
S_{k+1}^1 \\
\vdots \\
S_{k+1}^n \\
W_{k+1}
\end{array} \right) = \left( \begin{array}{c}
\theta_1(S_k, W_k, Z_{k+1}) \\
\vdots \\
\theta_n(S_k, W_k, Z_{k+1}) \\
\theta_{n+1}(S_k, W_k, Z_{k+1})
\end{array} \right)
\]  

(A.4)

and \( (S_k, W_k) \) verifies Eqs. (2.2)–(2.4). Here \( Z_{k+1} \) is defined in Eq. (A.2).

**Proof.** Let \( M_k \in ([R_+^*]^{n+1} \times R^n) \), defined in Eq. (A.1), and \( \xi_{k+1} \) be given, thus fixing the value of \( \phi_k = x_i M_{k+1}^i / M_k^i \). We can write Eq. (2.4) as

\[
M_{k+1}^i = A_i(M_k, Z_{k+1}) + \frac{1}{M_{k+1}^i} B_i(M_k, Z_{k+1}) M_{k+1}^{i+1}
\]  

(A.5)

for \( 1 \leq i \leq n \), where \( A_i \) and \( B_i \) are defined on \( ([R_+^*]^{n+1} \times R^n) \) by:

\[
A_i(M, Z) = M^i \exp(Z^i) \left( 1 - \frac{x_i M^{i+1}}{M^i D_i} \right)
\]  

(A.6)

\[
B_i(M, Z) = M^i \exp(Z^i) \frac{x_i}{D_i}
\]  

(A.7)

which implies that

\[
M_{k+1}^i = \frac{1}{2} (A_i(M_k, Z_{k+1}) + \sqrt{A_i^2(M_k, Z_{k+1}) + 4 B_i(M_k, Z_{k+1}) M_{k+1}^{i+1}}).
\]  

(A.8)

Reinjecting into Eq. (2.3), we find that \( M_{k+1}^{i+1} \) is a fixed point of the function

\[
v(x) = \frac{1}{2} \sum_{i=1}^n \frac{x_i M_{k+1}^{i+1}}{M_k^i} (A_i(M_k, Z_{k+1}) + \sqrt{A_i^2(M_k, Z_{k+1}) + 4 B_i(M_k, Z_{k+1}) x}).
\]  

(A.9)

Let us show that \( v \) has a unique fixed point on \( R_+^* \).
Institutional Investors and the Dependence Structure of Asset Returns

**Existence:** Given the expression of $v$, it is clear that for $x$ large enough, $v(x) < x$. We then examine the three following possibilities: there exists $i_0$ such that $A_{i_0}(M_k, Z_{k+1}) > 0$, which implies that $v(0) > 0$ and, as $v$ is a continuous function of $x$, that $v(x) > x$ for $x$ small enough; there exists $i_0$ such that $A_{i_0}(M_k, Z_{k+1}) = 0$, which implies that

$$v(x) \geq \frac{1}{2} x \frac{M_{k+1}^n}{M_k^n} \sqrt{4B_{i_0}(M_k, Z_{k+1})x}, \quad (A.10)$$

which is strictly larger than $x$ for $x$ small enough; and $\forall i A_i(M_k, Z_{k+1}) < 0$ which implies that $v(0) = 0$.

Let us then calculate:

$$v'(0) = \sum_{i=1}^{n} \frac{x_i M_k^{n+1}}{M_i^k} \frac{B_i(M_k, Z_{k+1})}{|A_i(M_k, Z_{k+1})|} = \sum_{i=1}^{n} \frac{x_i M_k^{n+1}}{M_i^k} \frac{\frac{x_i}{D_i}}{\frac{x_i M_k^{n+1}}{M_i^k} - 1}. \quad (A.11)$$

This implies that:

$$v'(0) > \sum_{i=1}^{n} \frac{x_i M_k^{n+1}}{M_i^k} \frac{\frac{x_i}{D_i}}{\frac{x_i M_k^{n+1}}{M_i^k}} = \sum_{i=1}^{n} x_i = 1 \quad (A.12)$$

assuming that $v(x) > x$ for $x$ small enough.

As $v$ is a continuous function of $x$, that $v(x) > x$ for large $x$ and $v(x) < x$ for small $x$, there exists at least one fixed point $x_0 > 0$ such that $v(x_0) = x_0$.

**Uniqueness:** Suppose that there exist two fixed points of function $v$, denoted $a$ and $b$ with $0 < a < b$. As $v$ is concave, for $0 < x < a$ we have $(v(a) - v(x))/(a - x) \geq (v(b) - v(a))/(b - a) = 1$, meaning that $x \geq v(x)$ which is in contradiction with the fact that $x < v(x)$ for $x$ sufficiently small. As a consequence, $v$ cannot have more than one fixed point. The unique fixed point of $v$ is $M_{k+1}^{n+1} > 0$ and we can deduce, for $1 \leq i \leq n$:

$$M_{k+1}^i = \frac{1}{2} A_i(M_k, Z_{k+1}) + \sqrt{A_i^2(M_k, Z_{k+1}) + 4B_i(M_k, Z_{k+1})M_{k+1}^{n+1}} > 0. \quad (A.13)$$

This proves Proposition 2.1. We now denote $\psi : (R_*^+)^{n+1} \times R^n \times R_*^+ \rightarrow R$ defined by:

$$\psi : (M, Z, x) \rightarrow x - \frac{1}{2} \sum_{i=1}^{n} \frac{x_i M_{k+1}^{n+1}}{M_i^k} (A_i(M, Z) + \sqrt{A_i^2(M, Z) + 4B_i(M, Z)x}), \quad (A.14)$$

where $A_i$ and $B_i$ are defined respectively in Eqs. (A.6) and (A.7), $\psi$ is $C^\infty$. Furthermore, we have $\psi(M, 0, M_{i+1}^{n+1}) = 0$ and $A_i(M, 0) = M_i(1 - (x_i M_{i+1}^{n+1})/(M_i^k D_i))$ and $B_i(M, 0) = M_i x_i / D_i$ according to Eqs. (A.6) and (A.7), which implies that

$$A_i^2(M, 0) + 4B_i(M, 0)M_{i+1}^{n+1} = \left( M_i \left( 1 + \frac{x_i M_{i+1}^{n+1}}{M_i^k D_i} \right) \right)^2. \quad (A.15)$$
Hence we find that:
\[
\frac{\partial \psi}{\partial x}(M, 0, M^{n+1}) = 1 - \sum_{i=1}^{n} \frac{x_i M^{n+1}}{M^i} \frac{B_i(M, 0)}{\sqrt{A_i^2(M, 0) + 4B_i(M, 0)M^{n+1}}} \quad (A.16)
\]
\[
= 1 - \sum_{i=1}^{n} x_i \frac{x_i M^{n+1}}{D_i + \frac{A_i M^{n+1}}{M^i}} \quad (A.17)
\]
\[
= \sum_{i=1}^{n} x_i - \sum_{i=1}^{n} x_i \frac{x_i M^{n+1}}{D_i + \frac{A_i M^{n+1}}{M^i}} \quad (A.18)
\]
\[
\frac{\partial \psi}{\partial x}(M, 0, M^{n+1}) = \sum_{i=1}^{n} \frac{x_i}{1 + \frac{x_i M^{n+1}}{D_i M^i}} > 0. \quad (A.19)
\]

As a consequence, if \( K \) is a compact set of \((\mathbb{R}_+^*)^{n+1} \), the implicit function theorem states that there exists \( \epsilon_K > 0 \) and \( \theta_{n+1} \) which is \( C^\infty \) on \( K \times B(0, \epsilon_K) \) such that:
\[
\psi(M, Z, \theta_{n+1}(M, Z)) = 0 \quad (A.20)
\]
and then, we deduce, for \( 1 \leq i \leq n \),
\[
\theta_i(M, Z) = \frac{1}{2}(A_i(M, Z) + \sqrt{A_i^2(M, Z) + 4B_i(M, Z)\theta_{n+1}(M, Z)}) \quad (A.21)
\]
and \( \theta_i \) is \( C^\infty \) on \( K \times B(0, \epsilon_K) \). This concludes the proof for the existence and smoothness of \( \theta \).

**A.2 Proof of Theorem 2.2**

Using Lemma A.1 and Cont & Wagalah (2013b, Sec. 6.1), we directly find the following lemma:

**Lemma A.2.** Under the assumption of Theorem 2.2, for all \( \epsilon > 0, r > 0 \):
\[
\lim_{\Delta t \to 0} \sup_{\|M\| \leq r} \frac{1}{\Delta t} \mathbb{P}([|M_{k+1} - M_k| \geq \epsilon |M_k = M]) = 0, \quad (A.22)
\]
\[
\lim_{\Delta t \to 0} \sup_{\|M\| \leq r} \frac{1}{\Delta t} \mathbb{E}(|M_{k+1} - M_k| |M_k = M) - b(M) = 0, \quad (A.23)
\]
\[
\lim_{\Delta t \to 0} \sup_{\|M\| \leq r} \frac{1}{\Delta t} \mathbb{E}((M_{k+1} - M_k)(M_{k+1} - M_k)' |M_k = M) - aa' \quad (A.24)
\]

where \( a \) and \( b \) are defined respectively in Eqs. (2.11) and (2.12).

The following lemmas are a direct consequence of the implicit function theorem and enable to compute \( a \) and \( b \) explicitly.
Lemma A.3. For $1 \leq l, i \leq n$:

\[
\frac{\partial \theta_i}{\partial z_l}(M, 0) = \frac{M^l}{1 + \frac{\partial M^{n+1}}{M' D_i}} \left( \delta_{l,i} + \frac{x_i M^{n+1}}{1 + \frac{\partial M^{n+1}}{M' D_i}} x_l \right), \tag{A.25}
\]

\[
\frac{\partial \theta_{n+1}}{\partial z_l}(M, 0) = \frac{M^{n+1}}{1 + \frac{\partial M^{n+1}}{M' D_i}} x_l. \tag{A.26}
\]

Proof. $\theta_{n+1}$ is defined implicitly by $\psi(M, Z, \theta_{n+1}(M, Z)) = 0$, where $\psi$ is given in Eq. (A.14). The implicit function theorem gives, for $1 \leq l \leq n$,

\[
\frac{\partial \theta_{n+1}}{\partial z_l}(M, Z) = \frac{-\partial \psi}{\partial z_l}(M, Z, \theta_{n+1}(M, Z)). \tag{A.27}
\]

Given the expression for $\psi$ given in Eq. (A.14), we find that

\[
\frac{\partial \psi}{\partial z_l}(M, Z, \theta_{n+1}(M, Z)) = -\frac{1}{2} x_i M^{n+1} \left( A_i(M, Z) + \frac{A_i^2(M, Z) + 2B_i(M, Z)}{\sqrt{A_i^2(M, Z) + 4B_i(M, Z)}} \right) \tag{A.28}
\]

and

\[
\frac{\partial \psi}{\partial x}(M, Z, \theta_{n+1}(M, Z)) = 1 - \sum_{i=1}^{n} \frac{x_i M^{n+1}}{M^l} \frac{B_i(M, Z)}{\sqrt{A_i^2(M, Z) + 4B_i(M, Z)}}. \tag{A.29}
\]

Using Eqs. (A.6) and (A.7), we find that

\[
A_i^2(M, Z) + 2B_i(M, Z) M^{n+1} = (M^l)^2 \left( 1 + \frac{M^{n+1}}{M' D_i} \right)^2. \tag{A.30}
\]

Given Eq. (A.15) and the fact that $\theta_{n+1}(M, 0) = M^{n+1}$, we find that

\[
\frac{\partial \psi}{\partial z_l}(M, 0, \theta_{n+1}(M, 0)) = -\frac{x_i M^{n+1}}{1 + \frac{\partial M^{n+1}}{M' D_i}}. \tag{A.31}
\]

Using Eqs. (A.27), (A.31) and (A.19), we find that

\[
\frac{\partial \theta_{n+1}}{\partial z_l}(M, 0) = \frac{M^{n+1}}{1 + \frac{\partial M^{n+1}}{M' D_i}} x_l. \tag{A.32}
\]

Let us now calculate, for $1 \leq i \leq n$ and $1 \leq l \leq n$, $\frac{\partial \theta_i}{\partial z_l}(M, 0)$. Given the definition of $\theta_i$, we remark that:

\[
\frac{\partial \theta_i}{\partial z_l}(M, Z) = -\frac{\partial \psi}{\partial z_l}(M, Z, \theta_{n+1}(M, Z)) \frac{\delta_{l,i}}{x_i M^{n+1}} + \frac{B_i(M, Z) \frac{\partial \theta_{n+1}}{\partial z_l}(M, Z)}{\sqrt{A_i^2(M, Z) + 4B_i(M, Z)x}} \tag{A.33}
\]
which, evaluated in 0 and given the expression for \( \frac{\partial \theta}{\partial z_l} \) and Eq. (A.15) gives:

\[
\frac{\partial \theta_i}{\partial z_l}(M, 0) = \frac{M^i}{1 + \frac{x_i M^{n+1}}{M^i D_i}} \left( \delta_{i,l} + \sum_{j=1}^{n} \frac{x_j M^{n+1}}{M^j D_j} \times \frac{x_j}{1 + \frac{x_i M^{n+1}}{M^i D_i}} \right). \tag{A.34} \]

Lemma A.4. For \( 1 \leq j, l \leq n \):

\[
\frac{\partial^2 \theta_{n+1}}{\partial z_j \partial z_l}(M, 0, M^{n+1}) = \delta_{j,l} x_l \left( \frac{M^i}{1 + \frac{x_i M^{n+1}}{D_i M^l}} \right) \left( 1 - \frac{2 \left( \frac{x_i M^{n+1}}{D_i M^l} \right)^2}{\left( 1 + \frac{x_i M^{n+1}}{D_i M^l} \right)^2} \right) \]

\[
+ \frac{2 x_j x_l}{\left( 1 + \frac{x_i M^{n+1}}{D_i M^l} \right) \left( 1 + \frac{x_j M^{n+1}}{D_j M^l} \right)} \sum_{1 \leq p \leq n} \frac{x_p}{1 + \frac{x_p M^{n+1}}{D_p M^l}} \left( \frac{x_p M^{n+1}}{D_p M^l} \right)^2 \]

\[
\times \left( \frac{x_j M^{n+1}}{D_j M^l} \right)^2 + \left( \frac{x_i M^{n+1}}{D_i M^l} \right)^2 \right) \]

\[
= \delta_{j,l} x_l \left( \frac{M^i}{1 + \frac{x_i M^{n+1}}{D_i M^l}} \right) \left( 1 - \frac{2 \left( \frac{x_i M^{n+1}}{D_i M^l} \right)^2}{\left( 1 + \frac{x_i M^{n+1}}{D_i M^l} \right)^2} \right) \]

\[
+ 2M^i \left( \frac{x_j M^{n+1}}{D_j M^l} \right)^2 \sum_{1 \leq p \leq n} \frac{x_p}{1 + \frac{x_p M^{n+1}}{D_p M^l}} \left( \frac{x_p M^{n+1}}{D_p M^l} \right)^3 \]

\[
\times \left( \delta_{j,l} x_l \left( \frac{M^i}{1 + \frac{x_i M^{n+1}}{D_i M^l}} \right) + \delta_{i,j} x_l \left( 1 + \frac{x_i M^{n+1}}{D_i M^l} \right) \right). \tag{A.35} \]
Proof. We first calculate for $1 \leq j, l \leq n$ $\frac{\partial^2 \theta_{n+1}}{\partial z_j \partial z_l}(M, 0)$. Deriving Eq. (A.28) with respect to $z_j$ gives the following equation:

$$
-2M l \left( \frac{x_{j} M^{n+1}}{\partial z_j M^l} \right)^2 + \frac{x_{l} M^{n+1}}{\partial z_l M^l} \left( \frac{\sum_{1 \leq p \leq n} \frac{x_p M^{n+1}}{1 + x_{p} M^{n+1}}} {1 + x_{j} M^{n+1}} \right)^2 \left( \frac{x_{j} M^{n+1}}{1 + x_{j} M^{n+1}} \right)
$$

$$
\frac{\partial^2 \theta_{n+1}}{\partial z_j \partial z_l}(M, 0). \quad (A.36)
$$

Considering Eq. (A.36), we find that if $l \neq j$, then $\frac{\partial^2 \theta_{n+1}}{\partial z_j \partial z_l}(M, 0, M^{n+1}) = 0$.

Deriving Eq. (A.28) with respect to $z_l$, we find that

$$
\frac{\partial^2 \psi}{\partial z_j \partial z_l}(M, Z, \theta_{n+1}(M, Z)) + \frac{\partial^2 \psi}{\partial x \partial z_l}(M, Z, \theta_{n+1}(M, Z)) \frac{\partial \theta_{n+1}}{\partial z_l}(M, Z)
$$

$$
+ \frac{\partial^2 \psi}{\partial x^2}(M, Z, \theta_{n+1}(M, Z)) \frac{\partial \theta_{n+1}}{\partial z_j}(M, Z) \frac{\partial \theta_{n+1}}{\partial z_l}(M, Z)
$$

$$
+ \frac{\partial \psi}{\partial x}(M, Z, \theta_{n+1}(M, Z)) \frac{\partial^2 \theta_{n+1}}{\partial z_j \partial z_l}(M, Z) = 0. \quad (A.37)
$$

Evaluating this equation in 0 and using Eqs. (A.31) and (A.15), we find that

$$
\frac{\partial^2 \psi}{\partial z_j \partial z_l}(M, 0, M^{n+1}) = \delta_{j,l} \frac{x_{j} M^{n+1}}{1 + x_{j} M^{n+1}} \left( 1 - \frac{x_{j} M^{n+1}}{M^l} \right)^2. \quad (A.40)
$$

Deriving Eq. (A.28) with respect to $x$, we find that

$$
\frac{\partial^2 \psi}{\partial z_j \partial x}(M, Z, x) = -\frac{2x_{j} M^{n+1}(M, Z)}{M^l} \frac{B^2_{l}(M, Z) x^2}{(A^2_{l}(M, Z) + 4B_{l}(M, Z)x)^2}. \quad (A.41)
$$

which, evaluated in 0, gives

$$
\frac{\partial^2 \psi}{\partial z_j \partial x}(M, 0, M^{n+1}) = -2x_{j} \left( \frac{M^{n+1}x_{j}}{M^l} \right)^2 \frac{1}{\left( 1 + \frac{M^{n+1}x_{j}}{M^l} \right)^3}. \quad (A.42)
$$
Differentiating Eq. (A.29) with respect to $x$, we find that
\begin{equation}
\frac{\partial^2 \psi}{\partial x^2}(M, Z, x) = 2 \sum_{1 \leq p \leq n} \frac{x_p M^{n+1}}{M^p} \frac{B_p^2(M, Z)}{(A_p^2(M, Z) + 4B_p(M, Z)x)^2} \tag{A.43}
\end{equation}
which implies that
\begin{equation}
\frac{\partial^2 \psi}{\partial x^2}(M, 0, M^{n+1}) = \frac{2}{M^{n+1}} \sum_{1 \leq p \leq n} \frac{x_p (x_p M^{n+1})^2}{(1 + \frac{x_p M^{n+1}}{B_p M^p})^2}. \tag{A.44}
\end{equation}

Using Eqs. (A.25), (A.26), (A.40), (A.42) and (A.44), the relationship given in Eq. (A.37) gives Eq. (A.35) of Lemma A.4.

Using Eq. (A.33), we can calculate the second order derivative of $\theta_i$ for $1 \leq i \leq n$. For $1 \leq j, l \leq n$:
\begin{equation}
\frac{\partial^2 \theta_i}{\partial z_j \partial z_l}(M, Z, \theta_{n+1}(M, Z))
= - \frac{\delta_{i,j}}{x_i M^{n+1}} \left( \frac{\partial^2 \psi}{\partial z_j \partial z_l}(M, Z, \theta_{n+1}(M, Z)) \right)
\end{equation}
\begin{equation}
= - \frac{\delta_{i,l}}{x_i M^{n+1}} \left( \frac{\partial^2 \psi}{\partial x \partial z_l}(M, Z, \theta_{n+1}(M, Z)) \frac{\partial \theta_{n+1}}{\partial z_l}(M, Z) \right)
\end{equation}
\begin{equation}
+ \delta_{i,j} \frac{\partial \theta_{n+1}}{\partial z_l}(M, Z) \frac{2B_p^2(M, Z)\theta_{n+1}(M, Z)}{(A_p^2(M, Z) + 4B_p(M, Z)\theta_{n+1}(M, Z))^2}
\end{equation}
\begin{equation}
= -2 \frac{B_p^2(M, Z)\theta_{n+1}}{(A_p^2(M, Z) + 4B_p(M, Z)\theta_{n+1}(M, Z))^2} \frac{\partial \theta_{n+1}}{\partial z_l}(M, Z)
\end{equation}
which, for $Z = 0$, gives Eq. (A.36). \hfill \Box

Define the differential operator $G : C_0^\infty(\mathbb{R}^{n+1}) \mapsto C_0^\infty(\mathbb{R}^{n+1})$ by
\begin{equation}
Gbh(x) = \frac{1}{2} \sum_{1 \leq i, j \leq n} (aa^t)_{i,j}(x) \partial_i h \partial_j h + \sum_{i=1}^n b_i(x) \partial_i h,
\end{equation}
where $a$ and $b$ are defined in Eqs. (2.11) and (2.12) respectively. $a$ and $b$ are continuous and Lemmas A.3 and A.4 show that for all $x \in \mathbb{R}^{n+1}$, $\|a(x)\| + \|b(x)\| \leq K\|x\|$. Ethier & Kurtz (1986, Theorem 2.6, Chap. 8) states that the martingale problem for $(G, \delta_{S_0, W_0})$ is well-posed. So, by Lemma A.2 and Ethier & Kurtz (1986, Theorem 4.2, Chap. 7), this implies that the process $(S_{\Delta t}, W_{\Delta t})$ converges in distribution to the solution $(\mathbb{P}, (P_t, V_t)_{t \geq 0})$ of the martingale problem for $(G, \delta_{S_0, W_0})$ when $\Delta t \to 0$.

Furthermore, as $a$ and $b$ are $C^\infty$, they are locally Lipschitz and hence, by Ikeda & Watanabe (1981, Theorem 3.1, Chap. 4), the solution of the martingale problem for $(G, \delta_{S_0, W_0})$ converges in distribution to the solution of the martingale problem for $(G, \delta_{S_0, W_0})$ when $\Delta t \to 0$.\n
\begin{equation}
1650010-30
\end{equation}
for \((G, \delta_{S_0, W_0})\) is the unique strong solution of the stochastic differential equation given in Theorem 2.2.

A.3 Proof of Proposition 3.1

We know that
\[
C_{[0,T]}^{i,j} = \frac{[\ln P^i, \ln P^j]}{T} = \frac{1}{T} \int_0^T c_s^{i,j} ds,
\]
where \(c_s\) is the derivative of the quadratic covariation and corresponds to the instantaneous covariance matrix of asset returns. By direct computation from Theorem 2.2 and Lemma A.3, we find that
\[
c_t = \Sigma + \Sigma (\Gamma_t - I_n) F_t + F_t (\Gamma_t - I_n) \Sigma
\]
\[+ F_t (\Gamma_t - I_n) \Sigma (\Gamma_t - I_n) F_t,
\]
where \(F_t\) and \(\Gamma_t\) are \(n \times n\) matrices such that \(F_t\) is diagonal with \(i\)th term equal to
\[
F_{i,i}^s = \frac{\Phi_{i,s} \Lambda_i}{1 + \Phi_{i,s}^p \Lambda_i},
\]
\[
\Gamma_{i,j}^s = \left( \sum_{1 \leq p \leq n} \frac{x_p}{1 + \Phi_{i,s}^p \Lambda_p} \right)^{-1} \frac{x_j}{1 + \Phi_{i,s}^j \Lambda_j},
\]
with \(\Phi_{i,s} = \frac{\delta_{i,s}}{s_0}\). This implies that
\[
C_{[0,T]} = \Sigma + \frac{1}{T} \int_0^T \left( \Sigma (\Gamma_s - I_n) F_s + F_s (\Gamma_s - I_n) \Sigma \right) ds
\]
\[+ \frac{1}{T} \int_0^T (F_s (\Gamma_s - I_n) \Sigma (\Gamma_s - I_n) F_s) ds,
\]
where \(F_s\) and \(\Gamma_s\) are defined in Eq. (A.48). We study the expression of \(C_{[0,T]}\) given in Eq. (A.49). Let us start with the term
\[
\frac{1}{T} \int_0^T (F_s (\Gamma_s - I_n) \Sigma) ds.
\]
We have
\[
[F_s (\Gamma_s - I_n)]_{i,k} = \frac{\Lambda_{i,s} \Phi_{i,s}^p}{1 + \Phi_{i,s}^p \Lambda_i} \left( \sum_{1 \leq p \leq n} \frac{x_p}{1 + \Phi_{i,s}^p \Lambda_p} \right)^{-1} \frac{x_k}{1 + \Phi_{i,s}^k \Lambda_k} - \delta_{i,k}
\]
which implies that
\[
\int_0^T [F_s (\Gamma_s - I_n) \Sigma]_{i,j} ds
\]
\[= \int_0^T \sum_{1 \leq k \leq n} [F_s (\Gamma_s - I_n)]_{i,k} \Sigma_{k,j} ds.
\]
\[ = - \int_0^T \frac{\Lambda_i \Phi_s^i}{1 + \Phi_s^i \Lambda_i} \Sigma_{i,j} ds \]
\[ + \int_0^T \frac{\Lambda_i \Phi_s^i}{1 + \Phi_s^i \Lambda_i} \sum_{1 \leq k \leq n} \left( \sum_{1 \leq p \leq n} \frac{x_p}{1 + \Phi_p^i \Lambda_p} \right)^{-1} \frac{x_k}{1 + \Phi_k(s) \Lambda_k} \Sigma_{k,j} ds. \]  

(A.53)

We then remark that
\[ \left| \int_0^T \frac{\Lambda_i \Phi_s^i}{1 + \Phi_s^i \Lambda_i} \Sigma_{i,j} ds - \int_0^T \Lambda_i \Phi_s^i \Sigma_{i,j} ds \right| \leq |\Sigma_{i,j}| A_i^2 \int_0^T \frac{(\Phi_s^i)^2}{1 + \Phi_s^i \Lambda_i} ds \]  

and hence
\[ \left| \int_0^T \frac{\Lambda_i \Phi_s^i}{1 + \Phi_s^i \Lambda_i} \Sigma_{i,j} ds - \int_0^T \Lambda_i \Phi_s^i \Sigma_{i,j} ds \right| \leq |\Sigma_{i,j}| A_i^2 \int_0^T (\Phi_s^i)^2 ds. \]  

(A.54)

Furthermore, we remark that:
\[ \left| \int_0^T \frac{\Lambda_i \Phi_s^i}{1 + \Phi_s^i \Lambda_i} \sum_{1 \leq k \leq n} \left( \sum_{1 \leq p \leq n} \frac{x_p}{1 + \Phi_p^i \Lambda_p} \right)^{-1} \frac{x_k}{1 + \Phi_k(s) \Lambda_k} \Sigma_{k,j} ds \right| \]
\[ - \int_0^T \Lambda_i \Phi_s^i \sum_{1 \leq k \leq n} x_k \Sigma_{k,j} ds \]  

\[ \leq \sum_{k=1}^n x_k |\Sigma_{k,j}| \int_0^T \Phi_s^i \Lambda_i \left| \frac{1}{1 + \Phi_s^i \Lambda_i} \frac{1}{1 + \Phi_k(s) \Lambda_k} \left( \sum_{1 \leq p \leq n} \frac{x_p}{1 + \Phi_p^i \Lambda_p} \right) \right|^{-1} ds \]  

(A.56)

\[ \leq \sum_{k=1}^n x_k |\Sigma_{k,j}| \int_0^T \frac{\Phi_s^i \Lambda_i}{(1 + \Phi_k(s) \Lambda_k)(1 + \Phi_s^i \Lambda_i)} \]  
\[ \times \left| \left( \sum_{1 \leq p \leq n} \frac{x_p}{1 + \Phi_p^i \Lambda_p} \right) \right|^{-1} \left( 1 + \Phi_k(s) \Lambda_k \right) \left( 1 + \Phi_s^i \Lambda_i \right) \]  

\[ \leq \sum_{k=1}^n x_k |\Sigma_{k,j}| \int_0^T \Phi_s^i \Lambda_i \]  
\[ \times \left| \left( \sum_{1 \leq p \leq n} \frac{x_p}{1 + \Phi_p^i \Lambda_p} \right) \right|^{-1} \left( 1 + \Phi_k(s) \Lambda_k \right) \left( 1 + \Phi_s^i \Lambda_i \right) \]  

(A.57)

(A.58)

(A.59)
where we used that
\[ \sum_{p=1}^{n} x_p = 1 \]  \hspace{1cm} (A.64)
and that for strictly positive real numbers \((y_i)_{1 \leq i \leq n}\), we have the convexity inequality
\[ \left( \sum_{p=1}^{n} \frac{x_p}{y_p} \right)^{-1} \leq \sum_{p=1}^{n} \frac{x_p}{y_p}. \]  \hspace{1cm} (A.65)

Given Lemmas A.3 and A.4, we find that, for \(1 \leq i, k \leq n\), \(a_{i,k}(P_t, V_t)/\beta_t^{n_i}\), \(a_{n+1,k}(P_t, V_t)/\beta_t^{n_i}\), \(b_i(P_t, V_t)/\beta_t^{m_i}\) and \(b_{n+1}(P_t, V_t)/\beta_t^{m_i}\), defined in Eqs. (2.11) and Eq. (2.12), are bounded uniformly in \(\Lambda\). As a consequence, by applying Itô’s formula to \((\phi(t)^{p}(\phi(t)^{q}(\phi(t)^{r}))^{s})\) for \(p, q, r \geq 0\), we find that \(\mathbb{E}((\phi(t)^{p}(\phi(t)^{q}(\phi(t)^{r}))^{s})) \leq K\exp(Ct)\) where \(C\) does not depend on \(\Lambda\).
As the largest eigenvalue of the fundamental correlation matrix, $v_1(0)$ is such that $(\tilde{R}(0))_{i,i} = 1$ and $(\tilde{R}(0))_{i,j} = \rho$ for $i \neq j$. As a consequence, it has a simple eigenvalue $v_1(0) = 1 + (n-1)\rho$, associated to the eigenvector $\psi_1(0) = 1/\sqrt{n} \times 1(1, \ldots, 1)$, and an eigenvalue of order $n-1$: $v_k(0) = 1 - \rho$ for $2 \leq k \leq n$, associated to eigenvectors $(\psi_k(0))_{2 \leq k \leq n}$, which form an orthonormal basis of the hyperplan of $\mathbb{R}^n$:

$$\mathcal{H} = \left\{ z \in \mathbb{R}^n \text{ s.t. } \sum_{i=1}^{n} z_i = 0 \right\}. \quad (A.69)$$

As the largest eigenvalue of the fundamental correlation matrix, $v_1(0)$, is a simple eigenvalue, we can use Proposition 3.3 to compute the largest eigenvalue and the first eigenvector of the realized correlation matrix of returns in the presence of feedback effects.

Given the parameters of our example, we find that for $i \neq j$

$$\nabla R_{i,j} = \tilde{\Lambda}(1-\rho)(\rho + 1 - \rho/n) \left( 2 + \int_0^T \left( 1 - \frac{s}{T} \right) d\Phi_i(s) + \int_0^T \left( 1 - \frac{s}{T} \right) d\Phi_j(s) \right). \quad (A.70)$$

We hence find the expression for $v(\tilde{\Lambda})$ given in Corollary 3.4 by direct computation of Proposition 3.3.
Proposition 3.3 states that the first eigenvalue of the realized correlation matrix of returns in the presence of feedback effects is given by:

\[ \psi_1 = \psi_1 + \frac{1}{n\rho} \sum_{k=2}^{n} \left( \overline{\psi_k} \nabla R \overline{\psi_1} \right) \overline{\psi_k} + o(\Lambda) \]  

(A.71)
as \( v_1(0) - v_k(0) = n\rho \) for \( k \geq 2 \). Given the fact that \( (\overline{\psi_k})_{2 \leq k \leq n} \) is an orthonormal basis of \( \mathcal{H} \) = defined in Eq. (A.69), the term

\[ \sum_{k=2}^{n} \left( \overline{\psi_k} \nabla R \overline{\psi_1} \right) \overline{\psi_k} \]  

(A.72)
is the orthogonal projection of \( \nabla R \overline{\psi_1} \) on \( \mathcal{H} \). Given the equation defining \( \mathcal{H} \), this orthogonal projection \( p_{\mathcal{H}} \) on \( \mathcal{H} \) is expressed as

\[
p_{\mathcal{H}}(z) = \begin{pmatrix}
    z_1 - \frac{1}{n} \sum_{1 \leq i \leq n} z_i \\
    \vdots \\
    z_n - \frac{1}{n} \sum_{1 \leq i \leq n} z_i
\end{pmatrix}.
\]  

(A.73)
Finally, as

\[
[\nabla R \overline{\psi_1}]_{\text{ia}} = \frac{1}{\sqrt{n}} \Lambda (1 - \rho) \left( \rho + \frac{1 - \rho}{n} \right) \sum_{j \neq i} \left( 2 + \Delta \Phi_j + \Delta \Phi_j^T \right)
\]  

(A.74)
and given the expression for \( p_{\mathcal{H}} \), we find the expression for \( \psi_1 \) given in Corollary 3.4.
